Keywords: Schroeder’s functional equation, iteration, composition operator,
several complex variables, Koenigs map, Hardy space, Bergman space

Abstract

In 1884 Koenigs showed that when \( \varphi \) is an analytic self-map of the unit
disk fixing the origin, with \( 0 < |\varphi'(0)| < 1 \), then Schroeder’s functional
equation, \( f \circ \varphi = \varphi'(0)f \), can be solved for a unique analytic function \( f \) in
the disk with \( f'(0) = 1 \). Here we consider a natural analog of Schroeder’s
equation in the unit ball of \( \mathbb{C}^N \) for \( N > 1 \), namely \( f \circ \varphi = \varphi'(0)f \) where
\( \varphi \) is an analytic self-map of the unit ball fixing the origin and \( f \) is to be a
\( \mathbb{C}^N \)–valued analytic map on the ball. Under some natural hypotheses on
\( \varphi \), we give necessary and sufficient conditions for the existence of a solution
\( f \) satisfying \( f'(0) = I \) and then describe all analytic solutions in the ball.
We also discuss various phenomena which may occur in the several variable
setting that do not occur when \( N = 1 \).

1 Introduction

When \( \varphi \) is an analytic map of the unit disk into itself, with \( \varphi(0) = 0 \) and \( \lambda = \varphi'(0) \) satisfying \( 0 < |\lambda| < 1 \), work of Koenigs [7] in 1884 gives an essentially unique solution \( f \) to Schroeder’s functional equation \( f \circ \varphi = \lambda f \) that is analytic in the disk. Koenigs realized \( f \) as the almost uniform limit of the sequence of normalized iterates \( \varphi_n/\lambda^n \) of \( \varphi \). When the Koenigs function \( f \) lies in an appropriate space of functions analytic on the disk (e.g., the Hardy space or the Bergman space), then \( f \) serves as an eigenvector for the composition operator \( C_\varphi \) acting on this space. Thus, the solutions of Schroeder’s equation play a basic role in the study of composition operators on spaces of functions analytic on the disk.

The goal of this paper is to consider a natural several variable version of Schroeder’s equation, with the unit ball in \( \mathbb{C}^N \) replacing the unit disk. Although several researchers have tried to generalize Koenigs’ original proof to this setting, no one has been successful with that approach. Instead, we will use the theory of compact composition operators on certain spaces of analytic functions in the ball to construct solutions to this several variable Schroeder’s equation under generous hypotheses, and show what difficulties can arise when \( N > 1 \) that are not present in the \( N = 1 \) case. We believe that these difficulties explain why no one has succeeded in extending Koenigs’ ideas to several variables.

Previous work on Schroeder’s equation in more than one variable has focused on the existence of formal power series solutions or local analytic solutions. For example, references [8], [13], [14], and [9, pp 332-336] discuss formal solutions or local analytic solutions and the obstruction that can arise when there are certain arithmetic relations among the eigenvalues of \( \varphi'(0) \). This work is closely related to the study of linearization of differential equations by a suitable change of variables (see, for example, [9, p 335]). This arises first in work of Poincaré [10, 11], with more recent descriptions in [6], [15] and [1, Chapter 5]. Since the derivative in the Schroeder equation case is the exponential of the derivative in Poincaré’s problem, the obstruction appears as a different arithmetic relation among the eigenvalues, which these authors call resonances. In these cases, too, the results concern the existence of formal or local changes of variable.

In contrast, our approach constructs global analytic solutions in the ball, without requiring any consideration of difficult issues of convergence of formal power series, by using the theory of compact composition operators on certain Hilbert spaces of functions analytic on the ball. This enables
us to give necessary and sufficient conditions, under mild hypotheses on $\varphi$, for the solution of a natural form of Schroeder’s functional equation in the ball. In particular, the global solutions are found to exist under no less general conditions than the formal power series solutions found by earlier researchers. With this approach, we find that the more subtle issue of the existence of an analytic solution in the ball that is locally univalent near the origin becomes a matter of the diagonalizability of certain matrices whose size depends on particular arithmetic relationships between the eigenvalues of $\varphi'(0)$; see Theorem 14.

We begin with a discussion of the desired form for a several variable analog of Schroeder’s equation. If $\varphi$ is an analytic map of the unit ball, $B_N$, into itself and $f$ is a $C^m$-valued, analytic function on the ball, then $f \circ \varphi$ is defined and is also a $C^m$-valued, analytic function on the ball. If we were to proceed by analogy with the one variable case where the Koenigs’ function is obtained as a limit of normalized iterates of the given map, since $\varphi$ and its iterates are $C^N$-valued, we would expect the unknown function in Schroeder’s equation to be $C^N$-valued. The multiplier on the right-hand side of Schroeder’s equation is a constant; in the several variable context, this constant might be a scalar, but it is more general to consider a constant matrix. Therefore, we are motivated to seek a $C^N$-valued analytic function $f$ for which

$$ f \circ \varphi = Af $$(1)

where $A$ is some $N \times N$ matrix. As in the one variable setting, we will also assume $\varphi(0) = 0$. If, for a mapping $f$ satisfying Equation (1), $f'(0)$ is invertible, then $f'(\varphi(0))\varphi'(0) = Af'(0)$, and it follows that $A = f'(0)\varphi'(0)f'(0)^{-1}$. Therefore, the equation $g \circ \varphi = \varphi'(0)g$ has the function $g = f'(0)^{-1}f$ as a solution. Notice that this substitution also gives $g'(0) = I$. Thus we will define our analog of Schroeder’s functional equation to be

$$ f \circ \varphi = \varphi'(0)f $$ (2)

and a solution $f$ of Equation (2) will be called a Schroeder map for $\varphi$. We will be primarily concerned with seeking Schroeder maps that are locally univalent near 0. By the above computation, the inverse function theorem, and its converse (see, for example, [12]), this is equivalent to the existence of a Schroeder map whose derivative at 0 is the identity.

Recall that “$\varphi$ unitary on a slice” means that there exist $\zeta$ and $\eta$ in $\partial B_N$ with $\varphi(\lambda \zeta) = \lambda \eta$ for all $\lambda$ in the unit disk, $D$. Since $\varphi$ maps $B_N$ into itself and $\varphi(0) = 0$, the Schwarz Lemma [12] implies $|\varphi'(0)| \leq 1$. Strict inequality
occurs precisely when \( \varphi \) is not unitary on any slice. This can be seen by considering the self-maps of the disk defined by \( g(\lambda) = \langle \varphi(\lambda \zeta), \eta \rangle \) for \( \zeta \) and \( \eta \) in \( \partial B_N \). Since \( g'(0) = \langle \varphi'(0) \zeta, \eta \rangle \), the one variable Schwarz Lemma gives the desired conclusion. To avoid certain pathologies, we will often assume that \( \varphi \) is not unitary on any slice. In particular, \( \varphi \) not unitary on any slice means \( |\varphi'(0)| < 1 \) which implies \( \varphi'(0) \) has no eigenvalue of modulus 1. As a consequence, if \( \varphi \) is not unitary on any slice and \( f \) solves Equation (2), then \( f(0) = 0. \)

The organization of the rest of the paper is as follows. In the next section we give some preliminary observations on Schroeder maps in several variables and then show how to build solutions to Schroeder’s equation from eigenfunctions for the composition operator \( C_\varphi \) when \( C_\varphi \) is compact on some weighted Hardy space; and conversely how to extract eigenfunctions for \( C_\varphi \) from Schroeder maps. In Section 3 we show that the hypotheses \( \varphi(0) = 0 \) and \( \varphi \) not unitary on any slice imply that \( C_\varphi \) will be compact on certain weighted Hardy spaces which are weighted Bergman spaces defined for weight functions that decay to 0 sufficiently rapidly. In Section 4 we give a number of examples of maps \( \varphi \) which either do or do not have Schroeder maps \( f \) satisfying the additional desired condition \( f'(0) = I \). In these examples certain arithmetic relationships hold between the eigenvalues of \( \varphi'(0) \) which can potentially make the existence of a locally univalent Schroeder map impossible. These examples are put into context in Section 5 where the main results (Theorems 13 and 14) give necessary and sufficient conditions for the existence of a Schroeder map satisfying \( f'(0) = I \) under natural hypotheses on \( \varphi \). Roughly speaking, the operative condition is the diagonalizability of a certain size upper left corner of the matrix for \( C_\varphi \) with respect to the standard, non-normalized orthogonal basis for a weighted Hardy space. From these results we are able to give a complete description of all Schroeder maps for \( \varphi \).

## 2 Solutions to Schroeder’s Equation

In one variable, the solutions to Schroeder’s equation are unique up to a multiplicative constant, and moreover, when \( \varphi \) is univalent in the disk, the Schroeder map will be univalent also. Both of these results can fail when \( N > 1 \). However, we do have the following restricted version of the latter result.

**Proposition 1** Let \( \varphi \) be an analytic map of \( B_N \) into itself such that \( \varphi \) is
not unitary on any slice of $B_N$, $\varphi(0) = 0$, and $A = \varphi'(0)$ is invertible. If $f$ is an analytic map of $B_N$ into $\mathbb{C}^N$ that solves Schroeder’s functional equation $f \circ \varphi = Af$ and $f'(0)$ is invertible, then $f$ is univalent on $B_N$ if and only if $\varphi$ is univalent on $B_N$.

**Proof.** Suppose first that $\varphi$ is not univalent, that is, suppose that $z$ and $w$ are distinct points of the ball for which $\varphi(z) = \varphi(w)$. The functional equation gives

$$Af(z) = f(\varphi(z)) = f(\varphi(w)) = Af(w)$$

Since $A$ is an invertible matrix, we see $f(z) = f(w)$ so that $f$ is not univalent either.

Conversely, suppose $f$ is not univalent on $B_N$ and $z$ and $w$ are distinct points of the ball for which $f(z) = f(w)$. Then, for every positive integer $n$,

$$f(\varphi_n(z)) = A^n f(z) = A^n f(w) = f(\varphi_n(w))$$

Since $f'(0)$ is invertible, there is a neighborhood of 0 on which $f$ is univalent. Since $\varphi$ is not unitary on a slice, the iterates of $\varphi$ tend to 0 and there is an $n$ large enough that $\varphi_n(z)$ and $\varphi_n(w)$ are both in this neighborhood. This means that $\varphi_n(z) = \varphi_n(w)$. Since $\varphi$ univalent on $B_N$ would imply $\varphi_n$ is also univalent, $\varphi$ cannot be univalent on $B_N$.

The linear fractional maps discussed in Section 4 show that the “only if” direction can fail if $A$ is not invertible. Example 3 in Section 4 shows that without the hypothesis that $f'(0)$ be invertible, the “if” direction of the above result need not hold.

In one variable the situation $\varphi'(0) = 0$ leads to a degenerate situation, since if $\varphi$ is not identically 0, the equation $f \circ \varphi = 0$ has only the trivial solution $f = 0$. In several variables we note the following consequence of a zero eigenvalue for $\varphi'(0)$:

**Proposition 2** Let $\varphi$ be a non-constant map of $B_N$ into itself with $\varphi(0) = 0$ and suppose 0 is an eigenvalue of $A = \varphi'(0)$. If $f$ is a solution of Schroeder’s functional equation $f \circ \varphi = Af$ such that $f$ is an analytic map of $B_N$ into $\mathbb{C}^N$ and $f'(0)$ is invertible, then there a neighborhood $\Omega$ of 0 such that $\varphi(\Omega)$ is contained in an $(N − 1)$–dimensional submanifold of $B_N$.

**Proof.** Suppose that $f$ is an analytic map of $B_N$ into $\mathbb{C}^N$ with $f'(0)$ invertible such that $f \circ \varphi = Af$. Let $v$ be an eigenvector of $A^*$ for the eigenvalue
0. Then it follows that

\[ \langle f(\varphi(z)), v \rangle = \langle Af(z), v \rangle = \langle f, A^*v \rangle = \langle f, 0 \rangle = 0 \]

This says that \( f \) maps the range of \( \varphi \) into the \( N - 1 \)-dimensional subspace orthogonal to \( v \). Since \( f' \) is continuous and \( f'(0) \) is invertible, there is a neighborhood of 0 on which \( f' \) is invertible also. The inverse function theorem then guarantees that \( f \) is one-to-one in some neighborhood of 0 and has an analytic inverse \( g \) in a neighborhood \( U \) of \( f(0) = 0 \). Thus, if \( \Omega = \varphi^{-1}(g(U)) \), then \( \varphi(\Omega) \) is contained in the submanifold \( g(U \cap [v]_+) \).

We will see later a non-trivial example of a map \( \varphi \) for which 0 is an eigenvalue of \( \varphi'(0) \), yet for which there is a univalent \( f \) solving \( f \circ \varphi = \varphi'(0)f \).

Our approach to constructing solutions to Schroeder’s Equation (2) will be through the theory of compact composition operators. A composition operator is defined from an analytic self-map \( \varphi \) of the ball by \( C_\varphi(g) = g \circ \varphi \) for \( g \) analytic in \( B_N \). In general we will be considering composition operators acting on weighted Hardy spaces \( H^2_\beta(B_N) \) in the ball. By definition, these are Hilbert spaces of analytic functions in \( B_N \) for which the monomials \( z^\alpha \), \( |\alpha| \geq 0 \), form a complete orthogonal set of non-zero vectors satisfying

\[ \beta(|\alpha|) \equiv \frac{\|z^\alpha\|}{\|z^0\|_2} = \frac{\|z^{\tilde{\alpha}}\|}{\|z^0\|_2} \]

whenever \( |\alpha| = |\tilde{\alpha}| \), where \( \|\cdot\| \) denotes the norm in \( H^2_\beta(B_N) \) and \( \|\cdot\|_2 \) denotes the norm in \( L^2(\sigma_N) \), \( \sigma_N \) being normalized Lebesgue measure on \( B_N \). Here \( \alpha \) is a multi-index \( (\alpha_1, \alpha_2, \ldots, \alpha_N) \), \( \alpha_j \geq 0 \) and \( |\alpha| = \sum \alpha_j \). If \( f = \sum_0^\infty f_s \) is the homogeneous expansion of a function analytic in \( B_N \), then \( f \) is in \( H^2_\beta(B_N) \) if and only if \( \|f\|^2 = \sum_0^\infty \|f_s\|_2^2 \beta(s)^2 < \infty \).

We will ordinarily write matrices for operators on \( H^2_\beta(B_N) \) with respect to the non-normalized orthogonal basis \( 1, z_1, z_2, \ldots, z_N, z_1^2, \ldots \). This “standard basis” is ordered in the usual way: \( z^\alpha \) precedes \( z^\gamma \) where \( \alpha = (\alpha_1, \ldots, \alpha_N) \) and \( \gamma = (\gamma_1, \ldots, \gamma_N) \) are multi-indices, if either \( |\alpha| < |\gamma| \) or, in the case \( |\alpha| = |\gamma| \), if there is a \( j_0 \) so that \( \alpha_j = \gamma_j \) for \( j < j_0 \) and \( \alpha_{j_0} > \gamma_{j_0} \); we write \( \alpha < \gamma \) in this case. If the \( j^{th} \) monomial in this ordering is \( z^\alpha \), then the \( j^{th} \) column of the matrix for \( C_\varphi \) has as its entries the coefficients of \( \varphi^\alpha \) with respect to this standard basis. This matrix is related to the matrix of \( C_\varphi \) with respect to the corresponding normalized basis by a diagonal similarity, given by the diagonal matrix with entries \( \|z^\alpha\| \).
It will sometimes be convenient to note that by a unitary change of variables we may assume that the matrix for $C_\varphi$ is lower triangular.

**Lemma 3** Let $\varphi : B_N \to B_N$ be analytic with $\varphi(0) = 0$. There is a map $\psi : B_N \to B_N$ with $C_\psi$ unitarily equivalent to $C_\varphi$ on any weighted Hardy space $H^2_\beta(B_N)$, for which the matrix of $C_\psi$ with respect to the standard basis is lower triangular.

**Proof.** Set $A = \varphi'(0)$. By the Schur theorem, there exists a $N \times N$ unitary matrix $U$ so that $UAU^{-1}$ is upper triangular. Set $\psi = U\varphi U^{-1}$, so that $\psi'(0)$ is the upper triangular matrix $UAU^{-1}$. Since the $jk$th entry of $\psi'(0)$ is $D_k\psi_j(0)$, this says that
\[
\psi_j(z) = a_{jj}z_j + \cdots + a_{jN}z_N + \text{higher order terms}
\]
The upper left corner of the matrix of $C_\psi$ is
\[
\begin{pmatrix}
1 & 0 \\
0 & \psi'(0)^t
\end{pmatrix}
\]
In general, the description of the coordinate functions of $\psi$ shows that if $\alpha > \beta$, for multi-indices $\alpha$ and $\beta$, then the coefficient of $z^\beta$ in the power series expansion of $\psi^\alpha$ is 0. Thus the matrix of $C_\psi$ is lower triangular. Moreover, the map $z \to Uz$ induces a bounded composition operator $C_U$ which is unitary on $H^2_\beta(B_N)$ (see, e.g. Lemma 8.1 of [3] ) and $C_\psi = C_U^{-1}C_\varphi C_U = C_U^{-1}C_\varphi C_U$.

An important tool for constructing solutions to Schroeder’s equation will be a result describing the spectra of compact composition operators on general weighted Hardy spaces $H^2_\beta(B_N)$.

**Theorem 4** ([3]) Suppose $\varphi : B_N \to B_N$ with $\varphi(0) = 0$. If $C_\varphi$ is compact on some weighted Hardy space $H^2_\beta(B_N)$, then the spectrum of $C_\varphi$ consists of 0, 1 and all possible products of the eigenvalues of $\varphi'(0)$.

We will see in Section 3 that the hypotheses $\varphi(0) = 0$ and $\varphi$ not unitary on any slice are sufficient to guarantee that $C_\varphi$ is compact on certain weighted Hardy spaces which are, in fact, weighted Bergman spaces. Thus, under these assumptions on $\varphi$ we will have, for each eigenvalue $\lambda_j$ of $\varphi'(0)$, an eigenfunction $\psi_j$, analytic in $B_N$, and satisfying $\psi_j \circ \varphi = \lambda_j \psi_j$. The next result shows how to use these to build a solution to Schroeder’s equation.
Theorem 5 Let \( \varphi : B_N \rightarrow B_N \) be analytic with \( \varphi(0) = 0 \). Suppose \( A = \varphi'(0) \) is diagonalizable, with eigenvalues \( \lambda_1, \ldots, \lambda_N \) and corresponding eigenvectors \( w_1, \ldots, w_N \). Suppose \( C_{\varphi} \) is compact on some weighted Hardy space \( H^2_{\beta} \), so that \( C_{\varphi} \) has eigenfunctions \( \psi_1, \ldots, \psi_N \) corresponding to \( \lambda_1, \ldots, \lambda_N \). Then

\[
f(z) = \psi_1(z)w_1 + \cdots + \psi_N(z)w_N
\]
is an analytic map of \( B_N \) into \( \mathbb{C}^N \) satisfying \( f \circ \varphi = Af \).

Conversely, if \( f \) satisfies \( f \circ \varphi = Af \) and if \( v_1, \ldots, v_N \) are eigenvectors for \( A^* \) with eigenvalues \( \overline{\lambda_1}, \ldots, \overline{\lambda_N} \), then \( \psi_j(z) = (f(z), v_j) \) satisfies \( \psi_j \circ \varphi = \lambda_j \psi_j(z) \).

**Proof.** Define \( f : B_N \rightarrow \mathbb{C}^N \) by \( f(z) = \psi_1(z)w_1 + \cdots + \psi_N(z)w_N \) where \( \psi_j \) is analytic in \( B_N \) with \( \psi_j \circ \varphi = \lambda_j \psi_j \) and \( w_j \) is in \( \mathbb{C}^N \) with \( Aw_j = \lambda_j w_j \). Then

\[
f \circ \varphi = \psi_1(\varphi(z))w_1 + \cdots + \psi_N(\varphi(z))w_N
\]
while

\[
\varphi'(0)f(z) = \varphi'(0)(\psi_1(z)w_1 + \cdots + \psi_N(z)w_N)
\]

\[
= \psi_1(z)\lambda_1 w_1 + \cdots + \psi_N(z)\lambda_N w_N
\]

\[
= f \circ \varphi
\]

This gives the first part of the theorem.

For the converse, suppose \( f : B_N \rightarrow \mathbb{C}^N \) is analytic with \( f \circ \varphi = \varphi'(0)f \) and let \( v_1, \ldots, v_N \) be eigenvectors of \( A^* = \varphi'(0)^* \) corresponding to the eigenvalues \( \overline{\lambda_1}, \ldots, \overline{\lambda_N} \). Define \( \psi_j(z) = (f(z), v_j) \). Then \( \psi_j \) is analytic on \( B_N \) and

\[
\psi_j(\varphi(z)) = (f(\varphi(z)), v_j) = (\varphi'(0)f(z), v_j)
\]

\[
= (f(z), A^*v_j) = (f(z), \overline{\lambda_j} v_j) = \lambda_j \psi_j
\]

\[
\square
\]

The hypothesis that \( A = \varphi'(0) \) is diagonalizable in Theorem 5 is not necessary. Without this assumption an analytic \( f \) solving Schröder’s equation can still be constructed from the (non-independent) eigenvectors of \( A \) and the eigenfunctions for \( C_{\varphi} \) as before. However since our ultimate interest is in solutions to Schröder’s equation which are locally univalent near 0, this leads us naturally to the additional requirement that \( \varphi'(0) \) be diagonalizable.
3 Compactness of Composition Operators

We show in this section that whenever \( \varphi : B_N \to B_N \) is analytic with \( \varphi(0) = 0 \) and \( \varphi \) not unitary on any slice, then \( C_\varphi \) is Hilbert-Schmidt, and thus compact, on the weighted Bergman space \( A^2_G(B_N) \) defined from a weight function which decays to 0 sufficiently rapidly as \( r \to 1 \), e.g. \( G(r) = \exp(-q/(1 - r)), \ q > 0 \). For \( G(r) \) a positive, continuous, non-increasing function on \([0, 1)\), the Bergman space \( A^2_G(B_N) \) is the space of analytic functions \( f \) on \( B_N \) for which

\[
\|f\|_G^2 = \int_{B_N} |f|^2 G(|z|) \, d\nu_N(z) < \infty
\]

where \( d\nu_N \) is volume measure on \( B_N \), normalized so that \( \nu_N(B_N) = 1 \). This is a weighted Hardy space \( H^2_\beta(B_N) \), where

\[
\beta(s) = \beta(|\alpha|) = \frac{||z^\alpha||_G}{||z^\alpha||_2}
\]

for any multi-index \( \alpha \). It will be convenient to say that \( G(r) \) is a fast regular weight if

\[
\lim_{r \to 1} \frac{G(r)}{(1 - r)^a} = 0
\]

for every \( a > 0 \), and moreover this ratio is decreasing for \( r \) near 1 for all \( a > 0 \).

Though for our purposes it will be enough to find a specific positive, continuous, and non-increasing weight function \( G \) so that \( C_\varphi \) is compact on the Bergman space \( A^2_G(B_N) \), the next two lemmas are easily done in the context of a general weighted Bergman space \( A^2_G(B_N) \). In the case \( N = 1 \) both of these lemmas appear, with similar proofs, in [3].

**Lemma 6** \( C_\varphi \) is Hilbert-Schmidt on \( A^2_G(B_N) \) if and only if

\[
\int_{B_N} \|K_\varphi(z)\|^2 G(|z|) \, d\nu_N(z) < \infty
\]

where \( K_w \) denotes the kernel function for evaluation at \( w \) in \( A^2_G(B_N) \).

**Proof.** Consider the orthonormal basis for \( A^2_G(B_N) \)

\[
\frac{z^\alpha}{||z^\alpha||_G} = \frac{z^\alpha}{\beta(|\alpha|)||z^\alpha||_2}
\]
where \( \alpha = (\alpha_1, \ldots, \alpha_N) \) is an multi-index and \( \| z^\alpha \|_2 \) denotes the \( L^2(\sigma_N) \) norm of \( z^\alpha \), given by

\[
\| z^\alpha \|_2^2 = \frac{(N - 1)! \alpha!}{(N - 1 + |\alpha|)!}
\]

where \( \alpha! = \alpha_1! \cdots \alpha_N! \). Thus \( C_\varphi \) is Hilbert-Schmidt if and only if

\[
\sum_\alpha \| C_\varphi(z^\alpha) \|^2 G \left( \frac{(N - 1 + |\alpha|)!}{\beta(|\alpha|)^2 (N - 1)! \alpha!} \right) < \infty
\]

Now

\[
\sum_\alpha \| C_\varphi(z^\alpha) \|^2 G \left( \frac{(N - 1 + |\alpha|)!}{\beta(|\alpha|)^2 (N - 1)! \alpha!} \right) = \sum_{s=0}^{\infty} \frac{(N - 1 + s)!}{\beta(s)^2 (N - 1)! s!} \sum_{|\alpha| = s}^{\infty} \frac{s!}{\alpha!} \| \varphi^\alpha \|^2 G
\]

where \( \varphi^\alpha(z) \) denotes \( \varphi_1(z)^{\alpha_1} \cdots \varphi_N(z)^{\alpha_N} \).

The inner sum has value

\[
\sum_{|\alpha| = s}^{\infty} \frac{s!}{\alpha!} \int_{B_N} |\varphi^\alpha|^2 G(|z|) \, d\nu_N(z) = \int_{B_N} \sum_{|\alpha| = s}^{\infty} \frac{s!}{\alpha!} |\varphi^\alpha|^2 G(|z|) \, d\nu_N(z)
\]

\[
= \int_{B_N} \langle \varphi(z), \varphi(z) \rangle^s G(|z|) \, d\nu_N(z)
\]

\[
= \int_{B_N} |\varphi(z)|^{2s} G(|z|) \, d\nu_N(z)
\]

by the multinomial theorem.

Thus (3) is equal to

\[
\sum_{s=0}^{\infty} \frac{(N - 1 + s)!}{(N - 1)! \beta(s)^2 s!} \int_{B_N} |\varphi(z)|^{2s} G(|z|) \, d\nu_N(z)
\]

\[
= \int_{B_N} \left( \sum_{s=0}^{\infty} \frac{(N - 1 + s)! |\varphi(z)|^{2s}}{(N - 1)! \beta(s)^2 s!} \right) G(|z|) \, d\nu_N(z)
\]

\[
= \int_{B_N} \| K_\varphi(z) \|^2 G(|z|) \, d\nu_N(z)
\]

since

\[
\| K_w \|^2 = \sum_{s=0}^{\infty} \frac{(N - 1 + s)! |w|^{2s}}{(N - 1)! s! \beta(s)^2}
\]

(see, for example, [5]).
Lemma 7 Let $G(r)$ be a positive, continuous, and non-increasing function on $[0, 1)$. Fix $b$ in $(0, 1)$. Then for any $z$ in $B_N$,
\[
\|K_z\|^2_G \leq (1 - b)^{-2N}(1 - |z|)^{-2N}[G(1 - b(1 - |z|))]^{-1}
\]

Proof. Fix $z$ in $B_N$ and let $\delta = (1 - b)(1 - |z|)$. Consider the ball $B_\delta(z)$ centered at $z$ with radius $\delta$. Since $\nu_N(B_\delta) = \delta^{2N}$, we have by the sub-mean value property
\[
|K_z(z)| \leq \frac{1}{\delta^{2N}} \int_{B_\delta(z)} |K_z(w)| \, d\nu_N(w)
\]
\[
= \frac{1}{\delta^{2N} \sqrt{G(|z| + \delta)}} \int_{B_\delta(z)} |K_z(w)| \sqrt{G(|z| + \delta)} \, d\nu_N(w)
\]
\[
\leq \frac{1}{\delta^{2N} \sqrt{G(|z| + \delta)}} \int_{B_\delta(z)} |K_z(w)| \sqrt{G(|w|)} \, d\nu_N(w)
\]
since $G$ is non-increasing. Now $d\nu_N(w)/\delta^{2N}$ is a probability measure on $B_\delta(z)$, so
\[
\left(\int_{B_\delta(z)} |K_z(w)| \sqrt{G(|w|)} \frac{d\nu_N(w)}{\delta^{2N}}\right)^2 \leq \int_{B_\delta(z)} |K_z(w)|^2 G(|w|) \frac{d\nu_N(w)}{\delta^{2N}}
\]
\[
\leq \frac{1}{\delta^{2N}} \|K_z\|^2_G
\]
which gives
\[
|K_z(z)|^2 = \|K_z\|^4_G \leq \frac{1}{G(|z| + \delta)} \frac{1}{\delta^{2N}} \|K_z\|^2_G
\]
or
\[
\|K_z\|^2_G \leq (1 - b)^{-2N}(1 - |z|)^{-2N}[G(1 - b(1 - |z|))]^{-1}
\]
by the definition of $\delta$. \hfill \blacksquare

Theorem 8 If $\varphi : B_N \to B_N$ is analytic with $\varphi(0) = 0$ and $\varphi$ is not unitary on any slice, then $C_\varphi$ is Hilbert-Schmidt on any Bergman space $A^2_G(B_N)$ for which $G$ is continuous, positive, and non-increasing on $[0, 1)$ satisfying
\[
\frac{G(r)}{(1 - r)^{2N}G(1 - \rho(1 - r))}
\]
is bounded near 1 for any $\rho > 1$. In particular, $C_\varphi$ is Hilbert-Schmidt on the Bergman space $A^2_G(B_N)$ for $G(r) = \exp(-q/(1 - r))$, $q > 0$. 

11
Proof. Since \( \varphi \) is not unitary on any slice, there exists \( r_0 < 1 \) and \( R > 1 \) so that
\[
\frac{1 - |\varphi(z)|}{1 - |z|} \geq R
\]
if \( r_0 \leq |z| < 1 \) ([5]). We will show that \( \|K_{\varphi(z)}\|^2 G(|z|) \) is bounded in \( r_0 \leq |z| < 1 \), and hence in \( B_N \); from this and Lemma 6 the result follows.

Choose \( b < 1 \) close enough to 1 so that \( bR > 1 \). For \( |z| \geq r_0 \) we have
\[
1 - |\varphi(z)| \geq R - R|z|
\]
and thus
\[
\|K_{\varphi(z)}\|^2_G = \|K_{\varphi(z)}\|^2_G \leq \|K_{1-R(1-|z|)}\|^2_G
\]
since \( \|K_w\| \) increases with \( |w| \). By Lemma 7 this is bounded above by
\[
\frac{(1 - b)^{-2N}(1 - (1 - R(1 - |z|)))^{-2N}}{G(1 - b(1 - R(1 - |z|)))}
\]
which is equal to
\[
\frac{(1 - b)^{-2N}R^{-2N}(1 - |z|)^{-2N}}{G(1 - bR(1 - |z|))}
\]
so that
\[
\|K_{\varphi(z)}\|^2 G(|z|) \leq \frac{G(|z|)}{(1 - b)^{2N}R^{2N}(1 - |z|)^{2N} G(1 - bR(1 - |z|))}
\]

The hypothesis on \( G(r)/(1 - r)^{2N} G(1 - \rho(1 - r)) \) guarantees this is bounded for \( r_0 \leq |z| < 1 \). Using \( G(|z|) = \exp(-q/(1 - |z|)) \), \( q > 0 \) a computation shows that this hypothesis on \( G(r) \) is satisfied.

4 Examples

We consider in this section some examples which show some of the complications that can arise in several variables, but are never present in one variable.

**Example 1** Let \( \varphi(z_1, z_2) = (\frac{1}{2} z_1, \frac{1}{4} z_2 + \frac{1}{2} z_1^2) \). Clearly \( \varphi \) maps \( B_2 \) into \( B_2 \) and is univalent. In the notation of Theorem 5 we set
\[
A = \begin{pmatrix} 1/2 & 0 \\ 0 & 1/4 \end{pmatrix}, \lambda_1 = 1/2, \lambda_2 = 1/4, w_1 = (1, 0)^t, w_2 = (0, 1)^t
\]
We seek eigenfunctions $\psi_1(z)$ and $\psi_2(z)$ for $C_\varphi$ corresponding to $\lambda_1$ and $\lambda_2$. Setting $\psi_1(z) = \sum c_\gamma z^\gamma$ we seek to solve

$$\psi_1 \circ \varphi = \frac{1}{2} \psi_1$$

in a neighborhood of 0. Note that since $\varphi(0) = 0$ we must have $\psi_1(0) = 0$. Order the multi-indices $\gamma$ as previously described. By comparing the power series expansions of the left and right-hand sides of Equation (4) we will show that the only solutions to this equation are $\psi_1(z) = cz_1$. To this end, suppose that $\psi_1$ is a different solution and let $\alpha$ be the least multi-index greater than $(1,0)$ for which $c_\alpha$ is non-zero, in the power series for $\psi_1$. Now

$$\psi_1 \circ \varphi = \sum_{\gamma} c_\gamma \varphi^\gamma = \sum_{\gamma=(\gamma_1,\gamma_2)} c_\gamma (\frac{1}{2} z_1)^{\gamma_1} (\frac{1}{4} z_2 + \frac{1}{2} z_1^2)^{\gamma_2}$$

We examine the multi-indices $\gamma$ for which the expansion of $c_\gamma (\frac{1}{2} z_1)^{\gamma_1} (\frac{1}{4} z_2 + \frac{1}{2} z_1^2)^{\gamma_2}$ will contribute a non-zero term of the form $kz^\alpha$. When $|\gamma| > |\alpha|$ a comparison of the total order in the terms of $c_\gamma (\frac{1}{2} z_1)^{\gamma_1} (\frac{1}{4} z_2 + \frac{1}{2} z_1^2)^{\gamma_2}$ shows that none are of the desired form. When $|\gamma| < |\alpha|$ the hypothesis that $c_\gamma = 0$ if $(1,0) < \gamma < \alpha$ yields no contribution of the form $kz^\alpha$, $k \neq 0$.

When $|\gamma| = |\alpha|$ we note that

$$c_\gamma (\frac{1}{2} z_1)^{\gamma_1} (\frac{1}{4} z_2 + \frac{1}{2} z_1^2)^{\gamma_2} = c_\gamma \frac{1}{2} z_1^{\gamma_1} \sum_{\beta_1+\beta_2=\gamma_2} c(\beta_1,\beta_2) (\frac{1}{4} z_2)^{\beta_1} (\frac{1}{2} z_1^2)^{\beta_2}$$

In order that any term in this is of the form $kz^\alpha$ we must have

- $\gamma_1 + 2\beta_2 = \alpha_1$
- $\beta_1 = \alpha_2$
- $\gamma_1 + \gamma_2 = \alpha_1 + \alpha_2$
- $\beta_1 + \beta_2 = \gamma_2$

which together imply $\alpha_1 = \gamma_1$ and $\alpha_2 = \gamma_2$. In other words, the only term $kz^\alpha$ arising from $c_\gamma \varphi^\gamma$ for $|\gamma| = |\alpha|$ occurs when $\gamma = \alpha$ and will be $c_\alpha \frac{1}{2}^{\alpha_1} \frac{1}{4}^{\alpha_2} z^\alpha$. Then Equation (4) implies that

$$\left(\frac{1}{2}\right)^{\alpha_1} \left(\frac{1}{4}\right)^{\alpha_2} = \frac{1}{2}$$
since our assumption is that $c_\alpha \neq 0$. This is impossible, since $\alpha > (1, 0)$. This contradiction shows that the only solutions to Equation (4) are $\psi_1(z) = cz_1$.

A similar analysis is possible in finding solutions to

$$\psi_2 \circ \varphi = \frac{1}{4} \psi_2 \quad (5)$$

Set $\psi_2 = \sum \gamma b_\gamma z^\gamma$ and note first that $\psi_2(0) = 0$. Comparing the coefficients of $z_1$ and $z_2^2$ on the left and right-hand sides of Equation (5) yields $b_\gamma = 0$ for $\gamma = (1, 0)$ and $(0, 1)$. Assume, for a contradiction, that there is a solution $\psi_2$ with a non-zero coefficient $b_\gamma$ for some multi-index $\gamma > (2, 0)$; let $\alpha$ denote the least such multi-index.

Again we determine for which $\gamma$, $b_\gamma z^\gamma$ will contribute a non-zero term of the form $kz^\alpha$. As before, a comparison of total orders shows there is no such contribution when $|\gamma| > |\alpha|$. If $|\gamma| < |\alpha|$ recall that $b_\gamma = 0$ if $\gamma = (1, 0), (0, 1)$ or if $(2, 0) < \gamma < \alpha$. Thus we can only have $|\gamma| < |\alpha|$ and $b_\gamma \neq 0$ if $\gamma = (2, 0)$. In this case, $b_\gamma \varphi^\gamma = b_\gamma (\frac{1}{2} z_1)^2$ and by our choice of $\alpha$ this is not of the form $kz^\alpha$.

Finally if $|\gamma| = |\alpha|$ consider

$$b_\gamma (\frac{1}{2} z_1)^{\gamma_1} (\frac{1}{4} z_2 + \frac{1}{2} z_1^{\gamma_2})$$

where

$$\left(\frac{1}{4} z_2 + \frac{1}{2} z_1^{\gamma_2}\right)^{\gamma_2} = \sum_{\beta_1 + \beta_2 = \gamma_2} c(\beta_1, \beta_2) (\frac{1}{4} z_2)^{\beta_1} (\frac{1}{2} z_1^{\gamma_2})^{\beta_2}$$

As before, the expansion of this contributes a term of the of the form $kz^\alpha$ only if

- $\gamma_1 + 2 \beta_2 = \alpha_1$
- $\beta_1 = \alpha_2$
- $\gamma_1 + \gamma_2 = \alpha_1 + \alpha_2$
- $\beta_1 + \beta_2 = \gamma_2$

which together imply $\alpha_1 = \gamma_1$ and $\alpha_2 = \gamma_2$. Thus the only term in $\sum b_\gamma \varphi^\gamma$ of the form $kz^\alpha$ comes from $\gamma = \alpha$ and is

$$b_\alpha \left(\frac{1}{2}\right)^{\alpha_1} \left(\frac{1}{4}\right)^{\alpha_2} z^\alpha$$
For Equation (5) to hold we must have
\[ \frac{1^{\alpha_1} 1^{\alpha_2}}{4} = \frac{1}{4} \]
but \( \alpha > (2, 0) \) so either \( \alpha_1 > 2 \), or \( \alpha_2 \geq 2 \), or \( \alpha_1 \) and \( \alpha_2 \) are both positive. Thus we have a contradiction.

Thus the only solutions to \( \psi_2 \circ \varphi = \frac{1}{4} \psi_2 \) are \( \psi_2(z) = b z^2_1 \).

By Theorem 5, we have solutions to Schroeder’s equation of the form \( f(z_1, z_2) = (a z_1, b z^2_1) \). The second part of Theorem 5 guarantees that this is a complete list of all solutions.

**Example 2** Let \( \varphi(z_1, z_2) = (c_1 z_1, c_3^3 z_2 + c_2 z^2_1) \) for non-zero values of \( c_1, c_2 \) that are small enough that \( \varphi \) maps \( B_2 \) into itself. Note that \( \varphi \) is univalent in \( B_2 \) and \( \varphi'(0) = \text{diag}(c_1, c^3_1) \). Furthermore, \( \psi_1(z) = z_1 \) is an eigenfunction of \( C_\varphi \) with eigenvalue \( c_1 \) and both \( \psi_2(z) = z^2_2 \) and \( \psi_3(z) = z_2 + c_2 z^2_1/(c^3_1 - c^2_1) \) are eigenfunctions of \( C_\varphi \) corresponding to \( c^3_1 \). Thus Schroeder’s equation has both a non-univalent solution
\[ f(z_1, z_2) = (z_1, z^3_1) \]
and a univalent solution
\[ f(z_1, z_2) = \left( z_1, z_2 + \frac{c_2 z^2_1}{c^3_1 - c^2_1} \right) \]

**Example 3: Linear Fractional Maps** Let \( \varphi \) be a linear fractional map of \( B_N \) into itself. This means \( \varphi \) can be written as
\[ \varphi(z) = \frac{A z}{\langle z, C \rangle + 1} \]
where \( A \) is an \( N \times N \) matrix, \( C \) and \( z \) are (column) vectors in \( \mathbb{C}^N \), and \( \langle \cdot, \cdot \rangle \) denotes the usual Euclidean inner product. Note that \( \varphi(0) = A \). The requirement that \( \varphi(B_N) \subset B_N \) implies that \( |C| < 1 \). The case \( C = 0 \) is uninteresting, so we assume \( C \neq 0 \). In [4] we showed that when \( A \) has no eigenvalue of modulus 1, there is a \( \mathbb{C}^N \)-valued \( f \) defined and univalent on \( B_N \) with \( f \circ \varphi = \varphi'(0) f \). Specifically,
\[ f(z) = \frac{z}{\langle z, P \rangle + 1} \]

15
where \( P = (I - A^*)^{-1}C \).

Note that for linear fractional maps \( \varphi \), we always get a univalent solution to Schroeder’s equation, regardless of the invertibility of \( \varphi'(0) \) or the univalence of \( \varphi \).

5 Codifying the Examples

In this section we give some general results which explain the examples in the previous sections. We begin with several lemmas.

**Lemma 9** If \( \lambda \) is an eigenvalue for an operator acting on some Hilbert space \( H_2^2(B_N) = M \oplus M^\perp \), where \( M = \text{span} \ z^\alpha, |\alpha| \leq m \) and \( M^\perp \) is its orthogonal complement. Suppose that with respect to this decomposition the operator has block matrix form

\[
T = \begin{pmatrix} X & Y \\ 0 & Z \end{pmatrix}
\]

where \( |\lambda| > \|Z\| \). Then \( \lambda \) is an eigenvalue of \( X \), and moreover, the multiplicity of \( \lambda \) as an eigenvalue of \( X \) is the same as its multiplicity as an eigenvalue of \( T \).

**Proof.** If

\[
\begin{pmatrix} X & Y \\ 0 & Z \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} = \lambda \begin{pmatrix} u \\ v \end{pmatrix}
\]

we must have \( Xu + Yv = \lambda u \) and \( Zv = \lambda v \). Now if \( |\lambda| > \|Z\| \) this says \( v = 0 \) and thus \( Xu = \lambda u \) as desired. Moreover, if

\[
w_j = \begin{pmatrix} u_j \\ v_j \end{pmatrix}
\]

are linearly independent eigenvectors for \( T \) corresponding to \( \lambda \), then by the above calculation \( v_j = 0 \) for each \( j \) and the \( u_j \)'s are linearly independent eigenvectors for \( X \). Conversely, given linearly independent eigenvectors \( u_j \) for \( X \), we have

\[
\begin{pmatrix} u_j \\ 0 \end{pmatrix}
\]

are linearly independent eigenvectors for \( T \). This gives the statement on multiplicities.

\[\square\]
Lemma 10 Suppose $A$ is an $n \times n$ lower triangular matrix and suppose $i = j_1, j_2, \cdots, j_k$ are the indices such that $a_{ii} = 0$. If the rank of $A$ is $n - k$, then there are vectors $v_1, v_2, \cdots, v_k$ that are orthogonal to the columns of $A$ such that $v_i(j_i) = 1$ and $v_i(\ell) = 0$ for $\ell > j_i$.

Proof. We will construct, inductively, a basis $w_1, w_2, \cdots, w_n$ for $\mathbb{C}^n$ consisting of columns of $A$ and vectors orthogonal to the columns of $A$ so that the vectors $v_i = w_{j_i}$ satisfy the conclusion of the theorem.

We assume, without loss of generality, that $1 \leq j_1 < j_2 < \cdots < j_k \leq n$. Let $A_i$ denote the $i^{th}$ column of $A$. Since the rank of $A$ is $n - k$, the columns $\{A_\ell : \ell \neq j_q, 1 \leq q \leq k\}$ are a basis for the range of $A$. If $v$ is a vector in $\mathbb{C}^n$, let $[v]_q$ be the vector in $\mathbb{C}^n$ such that $[v]_q(i) = v(i)$ for $1 \leq i \leq q$.

If $j_1 = 1$, that is, if $a_{11} = 0$, let $w_1 = (1,0,\cdots,0)^t$, but if $j_1 > 1$, that is, if $a_{11} \neq 0$, let $w_1 = A_1$. Then $[w_1]_1$ is a basis for $\mathbb{C}^1$.

Now suppose $w_1, w_2, \cdots, w_{p-1}$ have been chosen so that $[w_1]_{p-1}, [w_2]_{p-1}, \cdots, [w_{p-1}]_{p-1}$ form a basis for $\mathbb{C}^{p-1}$, and for $i \leq p - 1$, $w_i = A_i$ if $a_{ii} \neq 0$, but if $a_{ii} = 0$, then $w_i$ is orthogonal to the columns $\{A_\ell : \ell \neq j_q, 1 \leq q \leq k\}$, hence all the columns of $A$, $w_i(i) = 1$, and $w_i(\ell) = 0$ for $\ell > i$.

If $p = n + 1$, then the vectors $v_i = w_{j_i}$ for $i \leq k$ satisfy the conclusion of the theorem. On the other hand, suppose $p \leq n$. If $a_{pp} \neq 0$, let $w_p = A_p$. By the induction hypothesis, $[w_1]_{p-1}, \cdots, [w_{p-1}]_{p-1}$ is a basis for $\mathbb{C}^{p-1}$. Since $A$ is lower triangular, $[A_p]_{p-1} = 0$ and it follows that $[w_1]_p, \cdots, [w_{p-1}]_p, [w_p]_p$ are linearly independent. That is, they form a basis for $\mathbb{C}^p$ and the conclusion holds for $p$.

Now suppose $a_{pp} = 0$ so that $[A_p]_p = 0$. By the induction hypothesis, $[w_1]_{p-1}, \cdots, [w_{p-1}]_{p-1}$ is a basis for $\mathbb{C}^{p-1}$. This means that $[w_1]_p, \cdots, [w_{p-1}]_p$ span a $(p - 1)$-dimensional subspace of $\mathbb{C}^p$. Now let $u$ be a non-zero vector in $\mathbb{C}^p$ that is orthogonal to each of $[w_1]_p, \cdots, [w_{p-1}]_p$. In particular, $[w_1]_p, \cdots, [w_{p-1}]_p, u$ form a basis for $\mathbb{C}^p$. If $u(p) = 0$, then the vector $[u]_{p-1}$ is orthogonal to each of $[w_1]_{p-1}, \cdots, [w_{p-1}]_{p-1}$. This would mean that $[u]_{p-1} = 0$ and that $u = 0$. This contradiction implies $u(p) \neq 0$ and we may suppose that $u(p) = 1$. Then, we take $w_p$ to be the vector in $\mathbb{C}^n$ such that $[w_p]_p = u$ and $w_p(i) = 0$ for $i > p$. By construction, $w_p$ is orthogonal to $\{A_\ell : \ell < p$ and $\ell \neq j_q, 1 \leq q \leq k\}$. Moreover, because the first $p$ components of $A_i$ are 0 for $i \geq p$, $w_p$ is also orthogonal to $A_p, \cdots, A_n$. Thus, the conclusion holds for $p$ in this case as well.

By induction, then, the conclusion of the lemma holds. $\blacksquare$
Although we do not need the extra information, it is clear from the construction that the vectors \( v_i \) are orthogonal to each other. We will use the lemma to prove the existence of a nice basis for the nullspace of certain upper triangular matrices.

**Corollary 11** Suppose \( B \) is an \( n \times n \) upper triangular matrix and suppose \( i = j_1, j_2, \ldots, j_k \) are the indices such that \( b_{ii} = 0 \). If the nullity of \( B \) is \( k \), there is a basis, \( v_1, v_2, \ldots, v_k \), for the nullspace of \( B \) such that \( v_i(j_i) = 1 \) and \( v_i(\ell) = 0 \) for \( \ell > j_i \).

**Proof.** Apply Lemma 10 to the matrix \( B^* \) which is lower triangular. The lemma asserts the existence of the vectors \( v_1, v_2, \ldots, v_k \), such that \( v_i(j_i) = 1 \) and \( v_i(\ell) = 0 \) for \( \ell > j_i \) and such that \( v_1, v_2, \ldots, v_k \) are orthogonal to the range of \( B^* \). Since the orthogonal complement of the range of \( B^* \) is the nullspace of \( B \), these vectors are in the nullspace of \( B \). Since the vectors are clearly linearly independent and the nullity of \( B \) is \( k \), they form a basis for the nullspace of \( B \).

The proof of Lemma 10, which deals with lower triangular matrices, starts at the upper left corner of the matrix and works down to the lower right corner. It is clear that an analogous result is true for upper triangular matrices with an analogous proof starting at the lower right corner of the matrix and working up to the upper left corner. Using this result and duality as in the above corollary, we get the following corollary on constructing bases for the nullspaces of certain lower triangular matrices.

**Corollary 12** Suppose \( B \) is an \( n \times n \) lower triangular matrix and suppose \( i = j_1, j_2, \ldots, j_k \) are the indices such that \( b_{ii} = 0 \). If the nullity of \( B \) is \( k \), there is a basis, \( v_1, v_2, \ldots, v_k \), for the nullspace of \( B \) such that \( v_i(j_i) = 1 \) and \( v_i(\ell) = 0 \) for \( \ell < j_i \).

In the proofs of Theorems 13 and 14 we will let \( P_k \) denote the orthogonal projection of \( H^2_\beta(B_N) \) onto the subspace \( \text{span}\{z^\alpha : |\alpha| \leq k \} \) for \( k \) any positive integer. Let \( \mathcal{H}_k \) denote the abstract vector space spanned by the set \( \{z^\alpha : |\alpha| \leq k \} \). If we equip \( \mathcal{H}_k \) with the inner product arising from \( H^2_\beta(B_N) \), then \( \mathcal{H}_k \) is isometrically isomorphic to \( P_k H^2_\beta(B_N) \) and we denote by \( P \) the map from \( P_k H^2_\beta(B_N) \) onto \( \mathcal{H}_k \) that identifies polynomials; \( P \) is unitary if \( \mathcal{H}_k \) is regarded as a Hilbert space as above, and an isomorphism of vector spaces if it is regarded as an abstract vector space.
Now suppose \( \varphi : B_N \to B_N, \varphi(0) = 0 \), and \( A = \varphi'(0) \) is upper triangular. Then the matrix for \( C_\varphi \) on \( H_\beta^2(B_N) \) is lower triangular with respect to the standard orthogonal basis \( \{ z^\alpha \} \) for \( H_\beta^2(B_N) \) for any \( \beta \). Since \( C_\varphi^* \) has span\( \{ z^\alpha : |\alpha| \leq k \} \) as an invariant subspace, we have
\[
P_k C_\varphi^* P_k = C_\varphi^* P_k
\]
Taking adjoints gives
\[
P_k C_\varphi P_k = P_k C_\varphi
\]
From this we get the useful observation that if \( f \) is in the nullspace of \( C_\varphi - \lambda I \), then \( P_k f \) is in the nullspace of \( P_k C_\varphi P_k - \lambda I \), and if \( X \) is the matrix in the upper left-hand corner of the matrix for \( C_\varphi \) with dimensions \( K \times K \) where \( K = \dim H_k \), then \( PP_k f \) is in the nullspace of \( X - \lambda I \). Similar results apply if we fix a multi-index \( \tau \) and let \( P_\tau \) denote the orthogonal projection of \( H_\beta^2(B_N) \) on \( \text{span} \{ z^\alpha : \alpha \leq \tau \} \), and choose the size of \( X \) to correspond to the position of \( \tau \) in the standard ordering.

For the next result, recall that there is no loss of generality in assuming that \( A = \varphi'(0) \) is upper triangular, since Schroeder’s equation for \( \varphi \) has a locally univalent solution if and only if Schroeder’s equation for \( U \varphi U^{-1} \) for \( U \) unitary has a locally univalent solution. By Lemma 3, when \( A \) is upper triangular, the matrix for \( C_\varphi \) (with respect to the standard basis) is lower triangular.

**Theorem 13** Suppose \( \varphi \) is an analytic map of \( B_N \) into \( B_N \) with \( \varphi(0) = 0 \) and \( A = \varphi'(0) \) is upper triangular and diagonalizable, with diagonal entries \( \lambda_1, \lambda_2, \ldots, \lambda_N \) such that \( 0 < |\lambda_j| < 1 \). Assume further that \( \varphi \) is not unitary on any slice. Let \( X \) be any size square upper left corner of the matrix for \( C_\varphi \) with respect to the standard (non-normalized) basis for any weighted Hardy space \( H_\beta^2(B_N) \), ordered in the usual way.

If Schroeder’s equation has a solution \( f \) on \( B_N \) where \( f \circ \varphi = Af \) and \( f'(0) = I \), then \( X \) is diagonalizable.

**Proof.**
Suppose \( X \) is of size \( Q \times Q \). Find \( m \geq 1 \) so that \( M \equiv \dim H_m \geq Q \). If \( f \circ \varphi = Af \) where \( f'(0) = I \), write \( f = (f_1, f_2, \ldots, f_N) \). We may find a fast regular weight \( \hat{G}(r) \) with the property that \( \hat{G}(|z|) |f_j(z)| \leq 1 \) for all \( z \) in \( B_N \) and \( j = 1, 2, \ldots, N \). Set \( G(r) = (\hat{G}(r) \exp(-1/(1-r)))^{2m} \). A calculation shows that \( G(r) \) satisfies the hypothesis of Theorem 8 (Exercise 5.2.2 of [3] is relevant here). Thus \( C_\varphi \) is Hilbert-Schmidt, and hence compact, on \( A_\beta^2(B_N) \).
Using Corollary 11 we may choose a basis of eigenvectors $v_j$, with eigenvalues $\lambda_j$, for the diagonalizable upper triangular matrix $A^\ast$ with $v_j(j) = 1$ and $v_j(k) = 0$ for $k > j$. By Theorem 5 $\psi_j(z) \equiv \langle f(z), v_j \rangle$ is an eigenfunction for $C_\varphi$ with eigenvalue $\lambda_j$. Since by the choice of $\hat{G}$, each $f_k$ is in $A^2_G(B_N)$, and the $\psi_j$’s are linear combinations of the $f_k$’s, we have $\psi_j$ in $A^2_G(B_N)$. Moreover, any product of at most $m$ functions from the set \{\psi_1, \psi_2, \cdots, \psi_N\} will also be in $A^2_G(B_N)$.

By assumption, $f'(0) = I$, so the homogeneous expansion of $f_j$ is

$$f_j(z) = z_j + \text{higher order terms}$$

where “higher order terms” means terms of order greater than or equal to 2. Using this and the special form of the eigenvectors $v_j$ we see that

$$\psi_j(z) = a_{1j}^j z_1 + a_{2j}^j z_2 + \cdots + a_{j-1j}^j z_{j-1} + z_j + \text{terms of order at least 2}$$

Notice that the $\psi_j$’s are linearly independent, since if

$$\sum_{j=1}^N c_j \psi_j = 0 \quad (6)$$

we must have $c_N = 0$, since only $\psi_N$ contains a non-zero $z_N$ term. From this it follows that $c_{N-1} = 0$ since only $\psi_{N-1}$ and $\psi_N$ could contain non-zero $z_{N-1}$ terms. Continuing in this manner we see that each coefficient $c_j = 0$.

Now let $\tau$ be the $Q^{th}$ multi-index for $C_N$, with respect to the usual ordering. Consider the collection of all products $\psi^\gamma = \psi_1^{\gamma_1} \cdots \psi_N^{\gamma_N}$ where $\gamma \leq \tau$. Notice that each of these is a product of not more than $m$ of the $\psi_j$’s, counting repetitions, so that each of the products $\psi^\gamma, \gamma \leq \tau$ is in the collection

$$\psi_1, \psi_2, \cdots, \psi_N, \psi_1^2, \psi_1 \psi_2, \cdots, \psi_N^2, \psi_1^3, \cdots, \psi_N^m \quad (7)$$

of at most $m$–fold products of the $\psi_j$’s. These functions lie in $A^2_G(B_N)$, $C_\varphi$ is compact on $A^2_G(B_N)$, and any such product

$$\Pi^N \psi_j^{k_j} \text{ with } k_j \geq 0 \text{ and } \sum k_j \leq m$$

is an eigenfunction for $C_\varphi$ with eigenvalue

$$\Pi^N \lambda_j^{k_j}$$

20
We claim that this collection (7) of at most $m$-fold products is linearly independent. Suppose
\[ \sum c(\alpha)\psi^\alpha = 0 \] (8)
where $\psi^\alpha = \psi_1^{\alpha_1}\psi_2^{\alpha_2}\cdots\psi_n^{\alpha_n}$, $\sum \alpha_j \leq m$, $\alpha_j \geq 0$. If $|\alpha| \geq 2$ then from the form of the $\psi_j$’s we see that $\psi^\alpha$ contains no first order terms, so by comparing the coefficients of the first order terms in Equation (8) we see that
\[ \sum_{|\alpha| = 1} c(\alpha)\psi^\alpha = 0 \]
Since $\psi_1, \psi_2, \ldots, \psi_N$ are linearly independent, $c(\alpha) = 0$ for all $|\alpha| = 1$. Since this implies that only the terms with $|\alpha| = 2$ can contribute any second order terms, we must have
\[ \sum_{|\alpha| = 2} c(\alpha)\psi^\alpha = 0 \]
Note that among all multi-indices of total order 2, only for $\alpha = (0,0,\cdots,0,2)$ does $\psi^\alpha$ contain a non-zero $z_N^2$ term, so the corresponding coefficient $c(\alpha) = 0$. By next considering the $z_{N-1}z_N$ terms we see that the coefficient $c(\alpha)$ for $\alpha = (0,\cdots,0,1,1)$ must also be 0. Continuing in this manner we conclude that $c(\alpha) = 0$ for all $\alpha$ of total order 2, and hence Equation (8) becomes
\[ \sum_{|\alpha| \geq 3} c(\alpha)\psi^\alpha = 0 \]
Proceeding in the same manner we see that all coefficients $c(\alpha) = 0$ as desired.

Suppose $\lambda$ appears exactly $\ell$ times on the diagonal of $X$. Then $\lambda$ can be written in $\ell$ ways as a product $\Pi_1^N \lambda_j^{k_j}$ where $k_j \geq 0$ and the multi-index $(k_1,k_2,\ldots,k_N) \leq \tau$. We have produced in the above argument $\ell$ linearly independent eigenfunctions $\Pi_1^N \psi_j^{k_j}$ for $C\varphi$ with eigenvalue $\lambda$. Consider the projections $PP_\tau(\Pi_1^N \psi_j^{k_j})$ where $P_\tau$ denotes the projection of $H_\beta^2(B_N)$ onto span\{$z^\gamma : \gamma \leq \tau$\} and $P$ is the map from $P_\tau H_\beta^2(B_N)$ to this span (equipped with the inner product from $H_\beta^2(B_N)$) which identifies polynomials. The projections $PP_\tau(\Pi_1^N \psi_j^{k_j})$ are still linearly independent polynomials of degree $Q$, since the above independence argument only makes use of the terms of the functions $\Pi_1^N \psi_j^{k_j}$ corresponding to multi-indices $\leq \tau$, and these terms are still present in $PP_\tau(\Pi_1^N \psi_j^{k_j})$. Thus when $\lambda$ appears $\ell$ times on the diagonal of $X$ we have exhibited $\ell$ linearly independent eigenvectors in $C^Q$ for
X corresponding to the eigenvalue \( \lambda \). This shows \( X \) is diagonalizable.

Compare this result with Example 1 in the previous section, where \( \varphi(z_1, z_2) = (\frac{1}{2}z_1, \frac{1}{2}z_2 + \frac{1}{2}z_1^2) \). The eigenvalues there are \( \lambda_1 = \frac{1}{2} \) and \( \lambda_2 = \frac{1}{4} \). If \( X \) is the upper left 4 \( \times \) 4 corner of the matrix for \( C_\varphi \), \( X \) has diagonal entries \( \frac{1}{2}, \frac{1}{4}, \frac{1}{2}, \frac{1}{4} \) and one non-zero off-diagonal entry; namely a \( \frac{1}{2} \) in the 4 \( \times \) 3 position. This matrix is not diagonalizable, and by Theorem 13 there cannot exist an analytic \( f : B_2 \to C^2 \) with \( f \circ \varphi = \varphi'(0)f \) and \( f'(0) = I \). This agrees with our previous calculations in Example 1.

The hypothesis in Theorem 13 that \( A = \varphi'(0) \) is diagonalizable cannot be omitted. For example, consider the linear fractional map

\[
\varphi(z) = \frac{A z}{\langle z, C \rangle + 1}
\]

where

\[
A = \begin{pmatrix} \lambda & a \\ 0 & \lambda \end{pmatrix}
\]

where \( 0 < |\lambda| < 1, a \neq 0, \) and \( \lambda \) and \( |C| \neq 0 \) are chosen sufficiently small so that \( \varphi \) maps \( B_2 \) into itself. When \( a \neq 0, \) \( A \) is not diagonalizable. We know that there is a univalent solution to Schroeder’s equation of the form

\[
f(z) = \frac{z}{\langle z, P \rangle + 1}
\]

where \( P = (I - A^*)^{-1}C \). However the upper left 3 \( \times \) 3 corner of the matrix for \( C_\varphi \) is clearly not diagonalizable.

The main result of this section is a converse to Theorem 13 with a particular choice for \( X \).

**Theorem 14** Suppose \( \varphi \) is an analytic map of \( B_N \) into \( B_N \) with \( \varphi(0) = 0 \) and \( A = \varphi'(0) \) an upper triangular diagonalizable matrix, with diagonal entries \( \lambda_1, \lambda_2, \ldots, \lambda_N \) such that \( 0 < |\lambda_j| < 1 \). Assume further that \( \varphi \) is not unitary on any slice. Suppose that \( \lambda_j = \lambda_1^{k_1} \cdots \lambda_N^{k_N} \) is the longest expression (maximal \( \sum k_i \)) for one eigenvalue of \( A \) as a product of any number of the eigenvalues of \( A \). Set \( m = k_1 + \cdots + k_N \) and \( M = \) the number of multi-indices for \( C^N \) of total order less than or equal to \( m \); equivalently the dimension of \( \mathcal{H}_m \). Let \( M \) be the upper left \( M \times M \) corner of the matrix for \( C_\varphi \) with respect to the standard (non-normalized) basis for any weighted Hardy space \( H^2_\beta(B_N) \), ordered in the usual way. If \( M \) is diagonalizable, then Schroeder’s equation has a solution \( F \) with \( F'(0) \) invertible.
Note that we always have \( m \geq 1 \), since the relation \( \lambda_1 = \lambda_1 \) (for example) always holds, and that when \( m = 1 \) either all of the eigenvalues of \( \varphi'(0) \) are distinct, and none is a product of any number of the other eigenvalues, or some eigenvalues are repeated (\( \lambda_i = \lambda_j \) for some \( i \neq j \)), but none is a product of more than 1 of the other eigenvalues. When \( m = 1 \), \( M = N + 1 \) and the requirement that \( \mathcal{M} \) be diagonalizable is automatically satisfied by virtue of the hypothesis that \( \varphi'(0) \) is diagonalizable. So the existence of a Schroeder map which is univalent in a neighborhood of 0 is guaranteed in this case. Notice also that in the case that \( m = 1 \) and all eigenvalues of \( \varphi'(0) \) are distinct, the hypothesis in Theorem 14 on the diagonalizability of \( \varphi'(0) \) is automatically satisfied. On the other hand, one can construct linear fractional maps \( \varphi \) with \( \varphi'(0) \) not diagonalizable and yet \( \varphi \) has a Schroeder map with invertible derivative at the origin.

**Proof.** Since \( \varphi \) is not unitary on any slice, \( C_\varphi \) is compact on \( H^2_\beta(B_N) = A^2_G(B_N) \) for \( G(r) = \exp(-1/(1-r)) \) by Theorem 8. Let \( \lambda \) be any eigenvalue of \( \varphi'(0) \). Suppose \( \lambda \) appears \( j \) times on the diagonal of the lower triangular matrix for \( C_\varphi \). By our choice of \( M \), all \( j \) of these diagonal entries lie on the diagonal of \( M \). Choose \( M' \geq M \) so that

\[
C_\varphi^* \sim \begin{pmatrix} X & Y \\ 0 & Z \end{pmatrix}
\]

where \( X \) is size \( M' \times M' \) and \( \|Z\| < |\lambda_k| \) for \( k = 1, 2, \ldots, N \).

Now the multiplicity of \( \lambda \) as an eigenvalue of \( C_\varphi^* \) is the same as its multiplicity as an eigenvalue of \( X \), by Lemma 9. Since \( \mathcal{M}^* \) is diagonalizable and \( \lambda \) appears \( j \) times on the diagonal of \( \mathcal{M}^* \), there must be \( j \) linearly independent eigenvectors for \( \mathcal{M}^* \) corresponding to \( \lambda \). Since \( X \) is upper triangular, with \( \mathcal{M}^* \) in the upper left corner, these give rise to \( j \) linearly independent eigenvectors for \( X \). Thus the multiplicity of \( \lambda \) as an eigenvalue of \( C_\varphi^* \) is at least \( j \). Since \( \lambda \) appears \( j \) times on the diagonal of \( X \), the multiplicity of \( \lambda \) as an eigenvalue of \( X \) is no more than \( j \) and we have \( \dim \ker(C_\varphi^* - \lambda) = j \); by compactness of \( C_\varphi \) on \( A^2_G(B_N) \) we have \( \dim \ker(C_\varphi - \lambda) = j \).

Now suppose \( \lambda \) occurs in positions \( p_1, p_2, \ldots, p_j \) along the diagonal. Let \( f_1, f_2, \ldots, f_j \) be \( j \) linearly independent eigenfunctions for \( C_\varphi \) acting on \( A^2_G(B_N) \), with eigenvalue \( \lambda \). There is a \( q \geq m \) sufficiently large so that \( P_q f_1, P_q f_2, \ldots, P_q f_j \) are linearly independent vectors. Let \( Q \) be the number of multi-indices for \( C^N \) of total order less than or equal to \( q \) and let \( X' \) be the upper left \( Q \times Q \) corner of the matrix for \( C_\varphi \). Then \( PP_1 f_1, PP_1 f_2, \ldots, PP_1 f_j \) are a basis for \( \ker(X' - \lambda) \). By Corollary 12 we have a basis \( v_1, v_2, \ldots, v_j \).
for $\ker(X' - \lambda)$ with $v_l(p_l) = 1$ and $v_l(r) = 0$ for $r < p_l$. Write $v_l = b_1PP_qf_1 + \cdots + b_jPP_qf_j$ and set
\[ g_l^\lambda = b_1f_1 + \cdots + b_jf_j \]
so that $g_l^\lambda$ is an eigenfunction for $C_\phi$ in $A_{\alpha}^2(B_N)$, with eigenvalue $\lambda$, and $PP_q(g_l^\lambda) = v_l$ has its first non-zero entry a 1 in the $p_l^{th}$ position (since the eigenfunctions are all 0 at 0, we count so that the “1st” position corresponds to the coefficient of $z_1$).

By hypothesis, $\phi'(0)$ is diagonalizable. Let $W_1, W_2, \ldots, W_N$ be a basis of eigenvectors for $\phi'(0)$ corresponding to the eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_N$ and write $W_i = (W_i(1), W_i(2), \ldots, W_i(N))^t$. Let $W$ be the $N \times N$ matrix whose $i^{th}$ column is $W_i$.

We construct a $C^N$-valued analytic function $F$. First choose $N$ functions $G_1, G_2, \ldots, G_N$ as follows. For $1 \leq k \leq N$, if the $k^{th}$ diagonal entry of $\phi'(0)$ is the $i^{th}$ occurrence of $\lambda$ on the diagonal of $\phi'(0)$, let $G_k$ be $g_l^\lambda$. By construction, $G_k$ has leading term 1 in the $k^{th}$ position; i.e.
\[ G_k(z) = z_k + a_{k,k+1}z_{k+1} + \cdots + a_{k,N}z_N + \text{higher order terms} \]
For notational convenience define $a_{m,n} = 0$ if $1 \leq n < m \leq N$ and $a_{m,m} = 1$ for $1 \leq m \leq N$. Our desired analytic function $F$ is defined as
\[ F(z) = G_1(z)W_1 + G_2(z)W_2 + \cdots + G_N(z)W_N \]
By Theorem 5, $F$ satisfies $F \circ \phi = \phi'(0)F$.

We need only verify that $F'(0)$ is invertible. A computation shows that the first column of $F'(0)$ is $W_1$, the second column is $a_{12}W_1 + W_2$ and in general the $i^{th}$ column is $a_{i1}W_1 + a_{i2}W_2 + \cdots + a_{Ni}W_N = a_{i1}W_1 + a_{i2}W_2 + \cdots + W_i$ since $a_{ki} = 0$ if $k > i$ and $a_{ii} = 1$.

Denote the rows of $F'(0)$ generically by $R_1, R_2, \ldots, R_N$ and suppose some linear combination of the rows is 0, say
\[ c_1R_1 + c_2R_2 + \cdots + c_NR_N = 0. \]
Looking at the first entry of each row this yields
\[ c_1W_1(1) + c_2W_1(2) + \cdots + c_NW_1(N) = 0 \tag{9} \]
Using Equation (9) and considering next the second entry of each row gives
\[ a_{12}(c_1W_1(1)+c_2W_1(2)+\cdots+c_NW_1(N)) + c_1W_2(1)+c_2W_2(2)+\cdots+c_NW_2(N) \]
so that
\[ c_1 W_2(1) + c_2 W_2(2) + \cdots + c_N W_2(N) = 0. \tag{10} \]
Similarly, Equations (9) and (10) together with the description of \( F'(0) \) yield, by consideration of the third entries in each row,
\[ c_1 W_3(1) + c_2 W_3(2) + \cdots + c_N W_3(N) = 0. \]
Continuing, we see that if some linear combination of the rows of \( F'(0) \) is zero, the same linear combination of the rows of the matrix \( W \) is zero. By hypothesis \( W \) is invertible, so we must have \( c_1 = c_2 = \cdots = c_N = 0 \), which says that \( F'(0) \) is invertible as desired. \hfill \blacksquare

An examination of the proof of the theorem above also gives the following corollary.

**Corollary 15** Suppose \( \varphi \) is an analytic map of \( B_N \) into \( B_N \) with \( \varphi(0) = 0 \) and \( A = \varphi'(0) \) an upper triangular diagonalizable matrix. Assume further that \( \varphi \) is not unitary on any slice. If \( f \circ \varphi = \varphi'(0)f \) has a locally univalent solution, then for each number \( \lambda \), the dimension of \( \ker(C\varphi - \lambda I) \) is the number of times \( \lambda \) occurs on the diagonal of the matrix for \( C\varphi \). Conversely, if for each number \( \lambda \) the dimension of \( \ker(M - \lambda I) \) is the number of times \( \lambda \) occurs on the diagonal of \( M \), then \( f \circ \varphi = \varphi'(0)f \) has a locally univalent solution.

As we noted in Section 1, the existence of a solution to Schroeder’s equation with invertible derivative at 0 is equivalent to the existence of a solution with derivative equal to the identity. Thus when the hypotheses of Theorem 14 hold, Theorem 13 implies that every upper left corner of the matrix for \( C\varphi \) must be diagonalizable.

Theorem 14 explains the second example of Section 4. The eigenvalues are \( c_1 \) and \( c_3 \), so \( m = 3 \) and \( M = 10 \). The upper left \( 10 \times 10 \) corner of the matrix for \( C\varphi \) can be seen to be diagonalizable, consistent with our observation in Section 4 that a Schroeder map with invertible derivative at 0 exists.

**Corollary 16** Suppose the hypotheses of Theorem 14 hold and that in addition \( A = \varphi'(0) \) is diagonal. Then all solutions to Schroeder’s equation can be described as \( f = g \circ F \) where \( F \) is the Schroeder map, univalent in a neighborhood of 0, which was constructed in Theorem 14 and \( g = (g_1, g_2, \cdots, g_N) \)
is a mapping on $\mathbb{C}^N$ with polynomial coordinate functions. Moreover, if $g_k = \sum c(\gamma)z^\gamma$, then the coefficients $c(\gamma)$ are 0 unless $\lambda_k = \lambda_1^{\gamma_1} \lambda_2^{\gamma_2} \cdots \lambda_N^{\gamma_N}$, in which case $c(\gamma)$ can be chosen arbitrarily. If $\lambda_k$ appears $K$ times on the diagonal of the matrix of $C_\varphi$, then in $g_k$ all but $K$ of the coefficients of $g_k$ must be 0.

If $A = \varphi'(0)$ is merely diagonalizable, let $S$ be any matrix which diagonalizes $A$; i.e. $SAS^{-1} = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_N)$. Then an arbitrary Schroeder map has the form $S^{-1} \circ g \circ S \circ F$ with $F$ and $g$ as just described.

**Proof.** First suppose $\varphi'(0)$ is diagonal. Let $F : B_N \to \mathbb{C}^N$ be the Schroeder map constructed in Theorem 14 with $F'(0)$ invertible. Suppose $f : B_N \to \mathbb{C}^N$ is an arbitrary solution to $f \circ \varphi = \varphi'(0)f$. Since $F'(0)$ is invertible, $F$ is a univalent map of some neighborhood $V$ of 0 onto some neighborhood $W$ of 0, with analytic inverse in $W$. Hence, for each $z$ near 0, $\varphi'(0)z = F(\varphi(F^{-1}(z)))$ and we have

$$
(f \circ F^{-1})(\varphi'(0)z) = f(F^{-1}(\varphi'(0)z)) = f(F^{-1}(F(\varphi(F^{-1}(z)))) = f(\varphi(F^{-1}(z))) = \varphi'(0)(f \circ F^{-1})(z)
$$

so that $f \circ F^{-1}$ commutes with multiplication by the diagonal matrix $A = \varphi'(0) = \text{diag}(\lambda_1, \lambda_2, \cdots, \lambda_N)$. Let $g = f \circ F^{-1}$, a $\mathbb{C}^N$-valued analytic map in some neighborhood of 0. From the equation $gA = Ag$ we see that

$$
g(\lambda_1 z_1, \cdots, \lambda_N z_N) = (\lambda_1 g_1(z), \cdots, \lambda_N g_N(z))
$$

so that for $k = 1, 2, \cdots, N$

$$
g_k(\lambda_1 z_1, \cdots, \lambda_N z_N) = \lambda_k g_k(z)
$$

Writing $g_k$ in terms of its homogeneous expansion we see that the coefficient of $z^\gamma$ in $g_k$ is 0 if $\lambda_k \neq \lambda_1^{\gamma_1} \cdots \lambda_N^{\gamma_N}$ and the coefficient is arbitrary if $\lambda_k = \lambda_1^{\gamma_1} \cdots \lambda_N^{\gamma_N}$. Since the diagonal entries of the matrix for $C_\varphi$ are $1, \lambda_1, \lambda_2, \cdots, \lambda_N, \lambda_1^2, \lambda_1 \lambda_2, \cdots, \lambda_N^2, \lambda_1^3, \cdots$, the coefficients of $g_k$ must be zero except for the multi-indices corresponding to the diagonal entries which are equal to $\lambda_k$. This gives the desired form for an arbitrary Schroeder map when $\varphi'(0)$ is diagonal, and it is easy to see that any mapping in this form will be a Schroeder map for $\varphi$.

Now suppose that $A = \varphi'(0)$ is not diagonal, but is diagonalizable, with $SAS^{-1} = \Delta \equiv \text{diag}(\lambda_1, \lambda_2, \cdots, \lambda_N)$, and that the other hypotheses of Theorem 14 hold. We observe that $SfF^{-1}S^{-1}$ must commute with $\Delta$ on a
neighborhood of 0 whenever \( f \circ \varphi = Af \):

\[
(SfF^{-1}S^{-1})\Delta = SfF^{-1}S^{-1}(SAS^{-1}) \\
= SfF^{-1}AS^{-1} = SfF^{-1}(F\varphi F^{-1})S^{-1} \\
= Sf\varphi F^{-1}S^{-1} = SAfF^{-1}S^{-1} \\
= \Delta( SfF^{-1}S^{-1} )
\]

The calculations above show that \( SfF^{-1}S^{-1} = g \) where \( g_k \) is a polynomial with the coefficient of \( z^\gamma = 0 \) if \( \lambda_k \neq \lambda_1^\gamma \cdots \lambda_N^\gamma \) and arbitrary otherwise. So any Schroeder map \( f \) for \( \varphi \) has the form \( f = S^{-1}gSF \) for a polynomial mapping \( g \) as described. Conversely, a calculation shows that any such mapping \( S^{-1}gSF \) is a Schroeder map for \( \varphi \).
